

Strategy Blueprint: Opening High Breakout/Reversal (Paper-Test / Alert Mode)

1. Scope & Universe

- **Asset Class:** Equity Cash instruments.
- **Eligible Universe:** Only stocks that are actively traded in the Futures & Options (F&O) segment.
- **Timeframe:** 1-minute intraday candles.

2. Required Data Feeds

- **Historical Data:** The **Previous Day's High** (Previous_Day_High) taken from the prior session's daily chart.
- **Intraday Data:** Real-time 1-minute OHLCV (Open, High, Low, Close, Volume) data stream starting right at market open.

3. The Core Trigger Condition

The algorithm evaluates the market strictly on the **first 1-minute candle of the day (09:15:00 AM to 09:15:59 AM)**.

To trigger a valid setup, a single candle must satisfy two conditions simultaneously:

- **The Open Check:** The opening price of the 09:15 candle must be strictly **below** the Previous_Day_High.
- **The Close Check:** The closing price of that same 09:15 candle must be strictly **above** the Previous_Day_High.

Interpretation: The stock opens below yesterday's key high level, but aggressive buying pressure floods in during the first minute, driving the price completely through and closing above yesterday's high.

4. System Notification & Alert Rules (No Real Orders)

- **Direction:** Long (Buy) setup identification.
- **Alert Timestamp:** Exactly at **09:16:00 AM** (the moment the 09:15 candle closes and the second minute begins).
- **Action:** The system must **not** place any live orders. Instead, it must generate and send an instant real-time alert (via Telegram, desktop notification, or log file) containing:
 - Stock Symbol
 - Trigger Confirmation Status
 - Expected Entry Price (Open price of the 09:16 candle)

5. Risk Management & Target Calculation (Included in Alert)

To help you manually track and verify the setup's performance, the alert must also calculate and display:

- **Stop Loss (SL):** Set at the absolute lowest price reached during the 09:15 trigger candle (Low of the 09:15 bar).
- **Risk Value:** The monetary risk per share (Expected Entry Price minus Stop Loss).
- **Take Profit Target (TP):** Calculated automatically at a **1:2 Risk-Reward Ratio** (Expected Entry Price plus [2 times Risk]).
